# Quantum Matter meets Quantum Computing

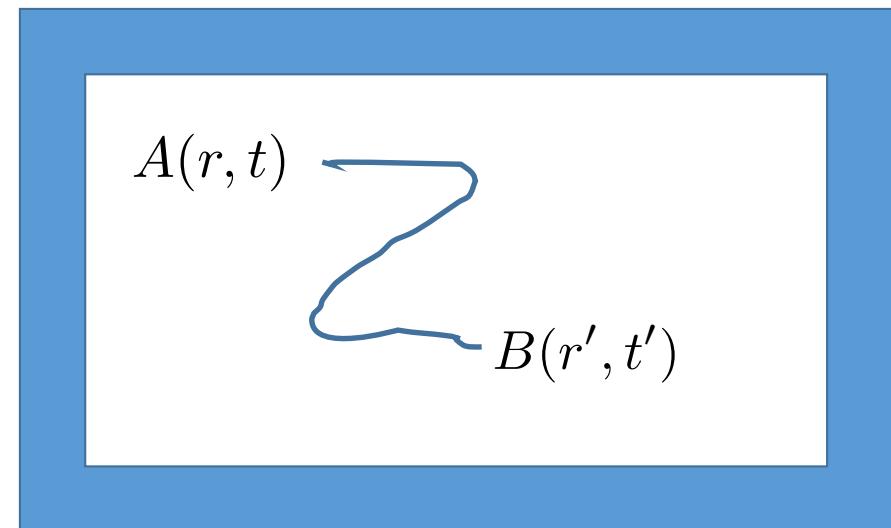

- Experimental relevance:  
Measuring correlation functions
- Preparing/measuring topological states
- Driven/dissipative systems and fixed points
- Time evolution via Lie algebraic decomposition and compression
- Thermodynamics
- Physics-Informed Subspace Expansions

## Low-energy excitations: correlation functions

$$\langle A(r, t)B(r', t') \rangle$$

*Given some (observable) operator B at (r',t'), what is the likelihood of some (observable) operator A at (r,t)?*

Conductivity

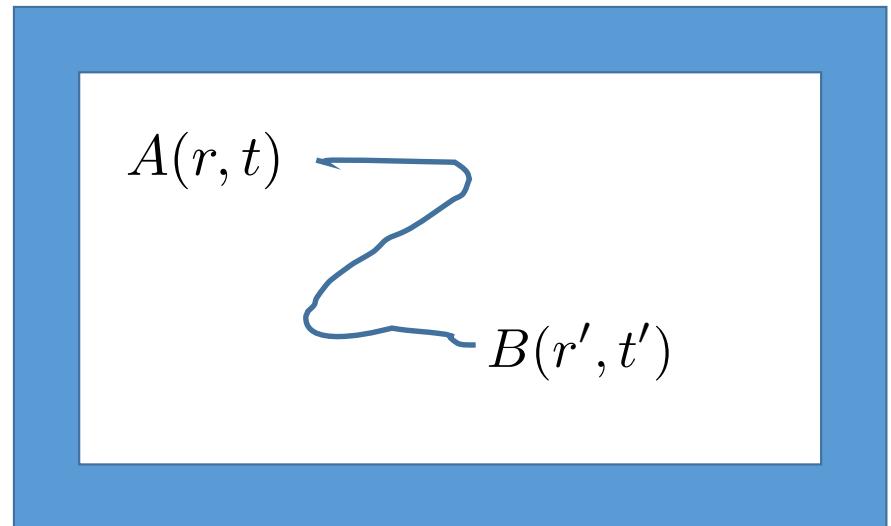

$$\langle j(r, t)j(r', t') \rangle$$

Single-particle spectra (ARPES)

$$\langle c(r, t)c^\dagger(r', t') \rangle$$

Spin-resolved neutron scattering

$$\sigma_{\alpha\beta}^{x,y,z} \langle S_\alpha(r, t)S_\beta(r', t') \rangle$$

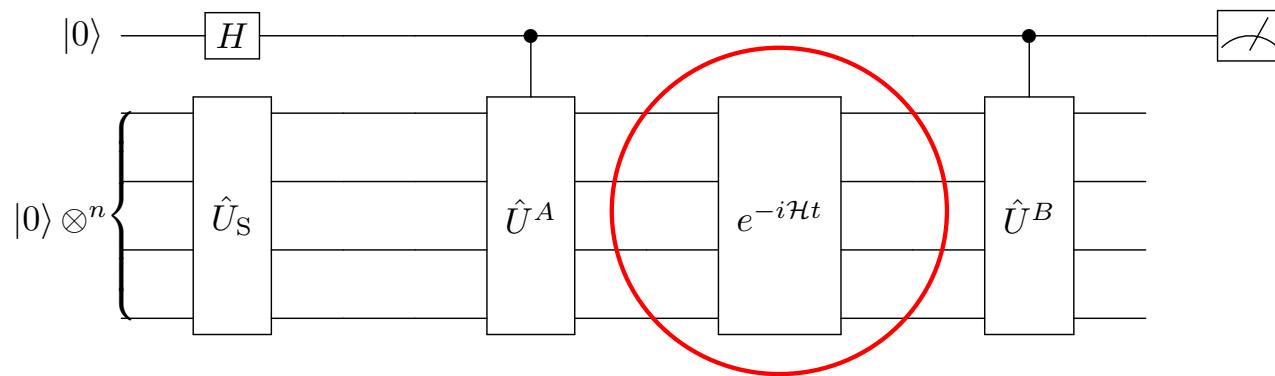

# Low-energy excitations: correlation functions

Express the correlation function through the Lehmann representation:

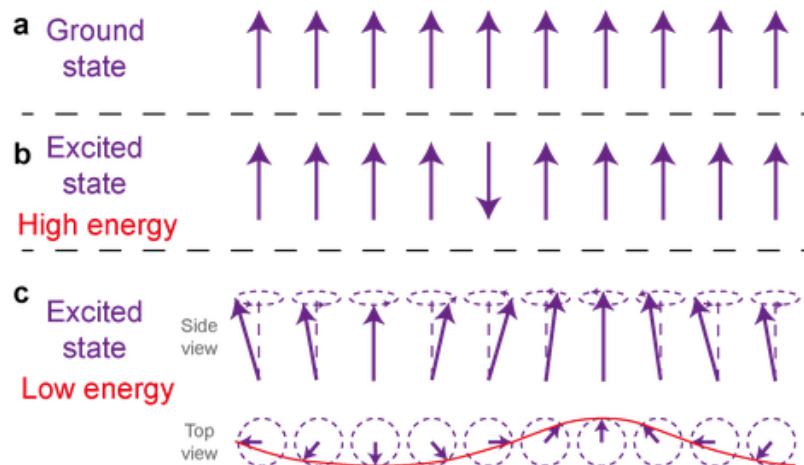

$$C(t) = \langle \Phi | \hat{U}^B(t) \hat{U}^A(0) | \Phi \rangle = \sum_m e^{-i(E_m - E_0)t} \langle \phi_0 | U^B | m \rangle \langle m | U^A | \phi_0 \rangle.$$

Quantum circuit:

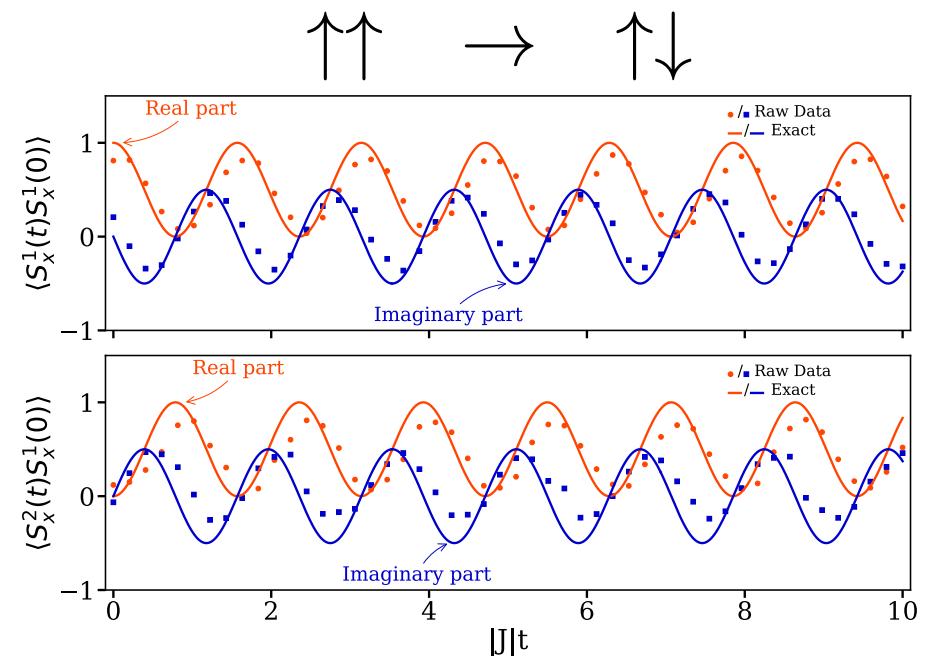

# Low-energy excitations: 2-site magnons

Spin-spin correlation function for periodic Heisenberg model: Magnons!

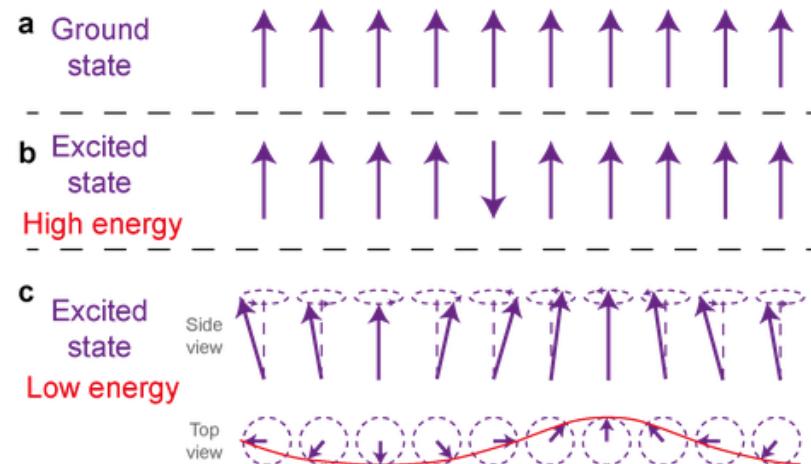

$$\hat{H} = 2SJ \sum_k (1 - \cos(k)) \hat{c}_k^\dagger \hat{c}_k$$

Data from *ibmq\_tokyo*

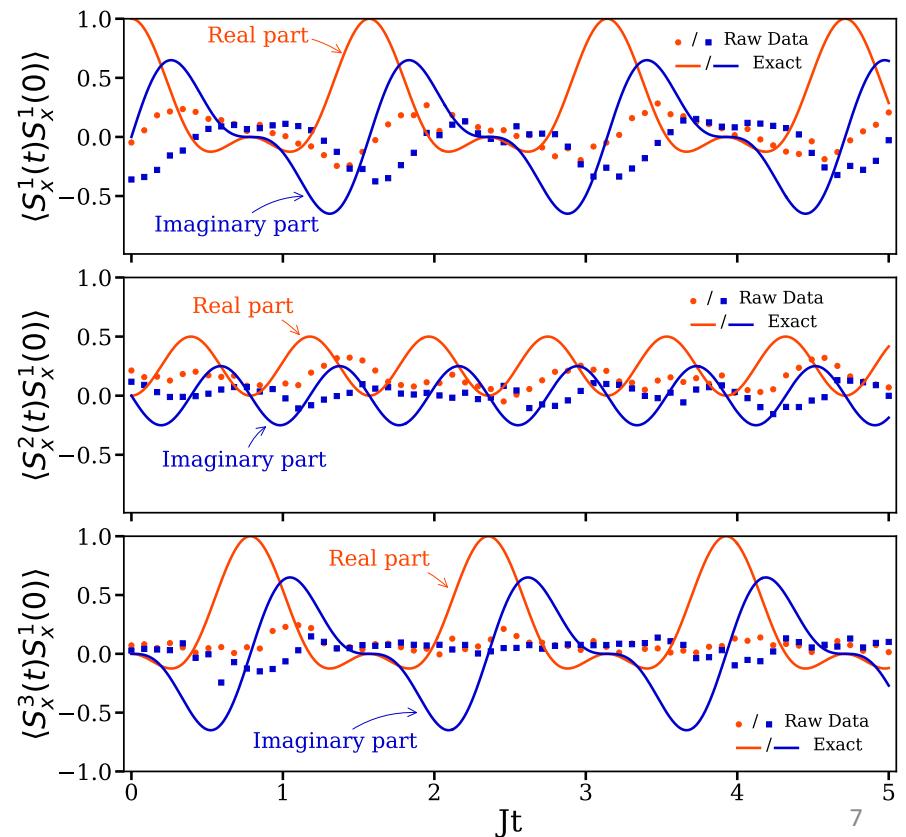

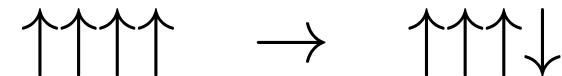

# Low-energy excitations: 4-site magnons

Spin-spin correlation function for periodic Heisenberg model

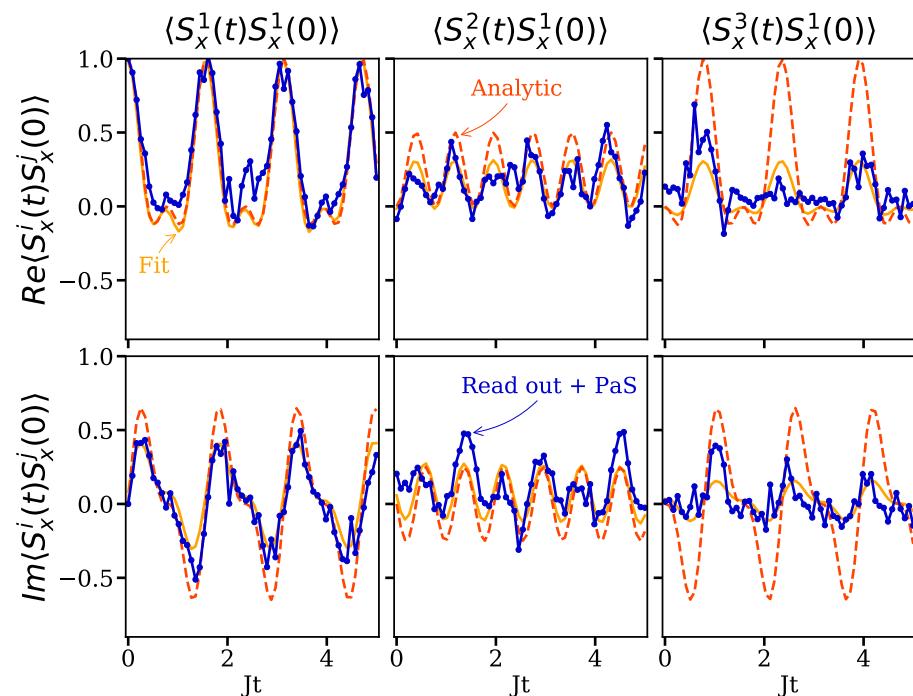

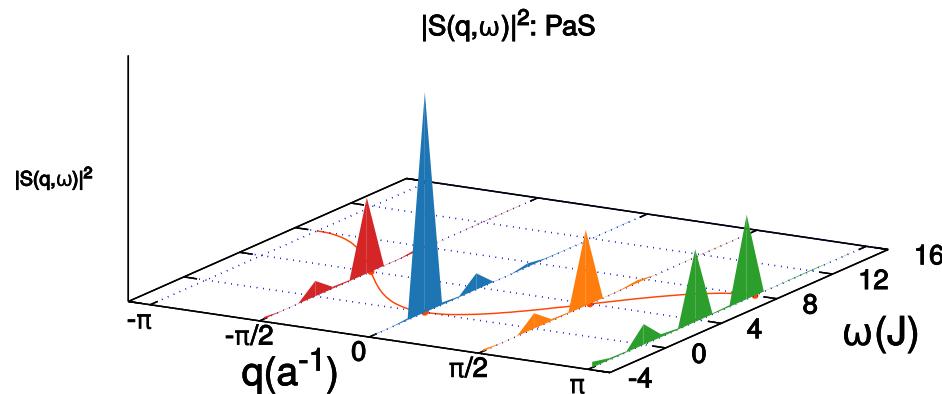

$$\hat{H} = 2SJ \sum_k (1 - \cos(k)) \hat{c}_k^\dagger \hat{c}_k$$

Data from *ibmq\_tokyo*

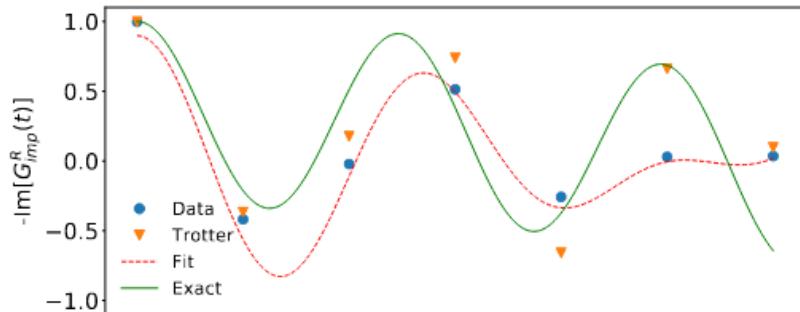

# Low-energy excitations: 4-site magnons

Spin-spin correlation function for periodic Heisenberg model: Magnons!

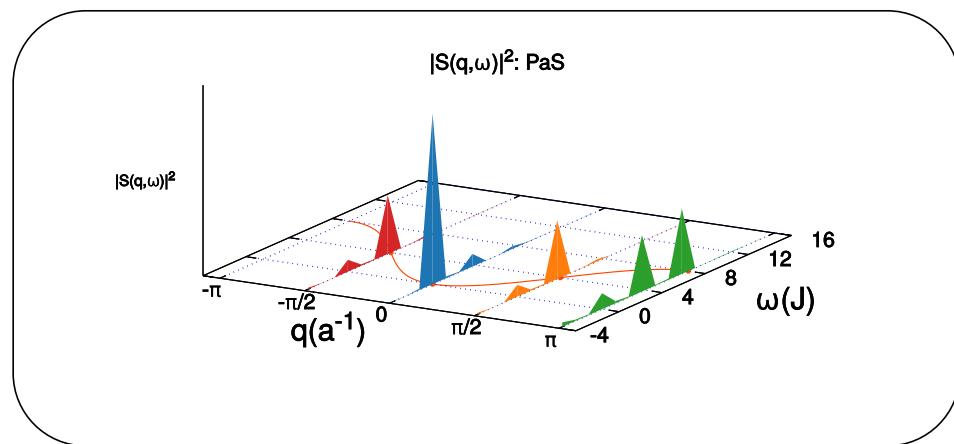

# Low-energy excitations: 4-site magnons

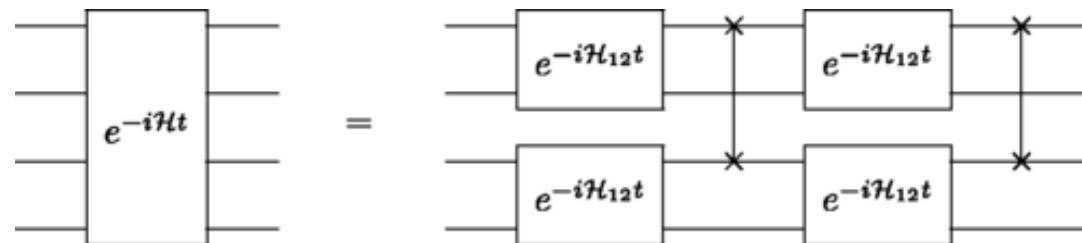

Q: Why does this work?

Keen et al., QST [10.1088/2058-9565/ab7d4c](https://doi.org/10.1088/2058-9565/ab7d4c)

A: Constant depth time evolution circuits

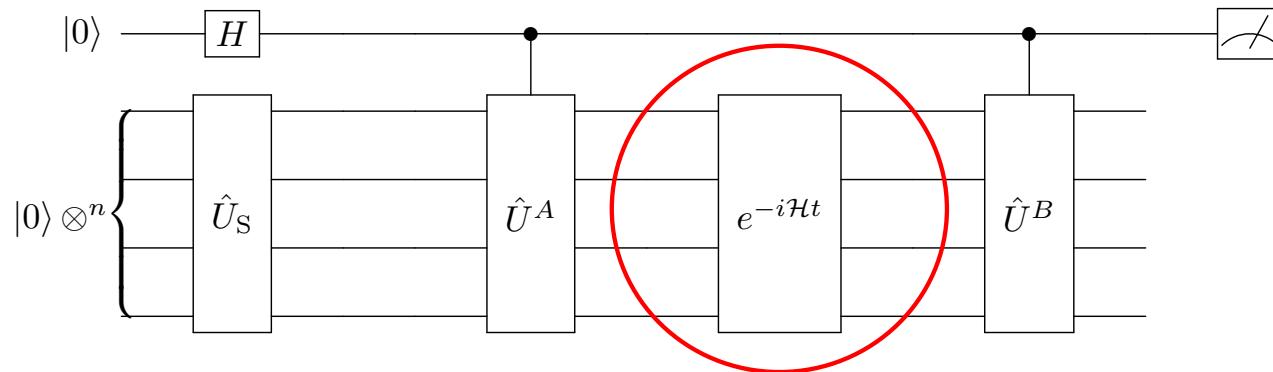

# Low-energy excitations: correlation functions

Express the correlation function through the Lehmann representation:

$$C(t) = \langle \Phi | \hat{U}^B(t) \hat{U}^A(0) | \Phi \rangle = \sum_m e^{-i(E_m - E_0)t} \langle \phi_0 | U^B | m \rangle \langle m | U^A | \phi_0 \rangle.$$

Quantum circuit:

## Trotter Approximation

Consider 5 spin Kitaev chain:

$$\mathcal{H} = a XXIII + b IYYII + c IIXXI + d IIIYY$$

$$U(t) = e^{-it\mathcal{H}} \neq e^{-ita} XXIII e^{-itb} IYYII e^{-itc} IIXXI e^{-itd} IIIYY$$

## Trotter Approximation

Consider 5 spin Kitaev chain:

$$\mathcal{H} = a \text{ } XXIII + b \text{ } IYYII + c \text{ } IIIXXI + d \text{ } IIIYY$$

$$U(\epsilon) = e^{-i\epsilon\mathcal{H}} = e^{-i\epsilon a} XXIII e^{-i\epsilon b} IYYII e^{-i\epsilon c} IIIXXI e^{-i\epsilon d} IIIYY + O(\epsilon^2)$$

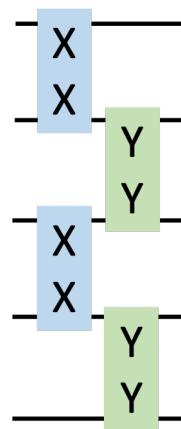

## Trotter Approximation

Consider 5 spin Kitaev chain:

$$\mathcal{H} = a XXIII + b IYYII + c IIXXI + d IIIYY$$

$$U(\epsilon) = e^{-i\epsilon\mathcal{H}} = e^{-i\epsilon a} XXIII e^{-i\epsilon b} IYYII e^{-i\epsilon c} IIXXI e^{-i\epsilon d} IIIYY + O(\epsilon^2)$$

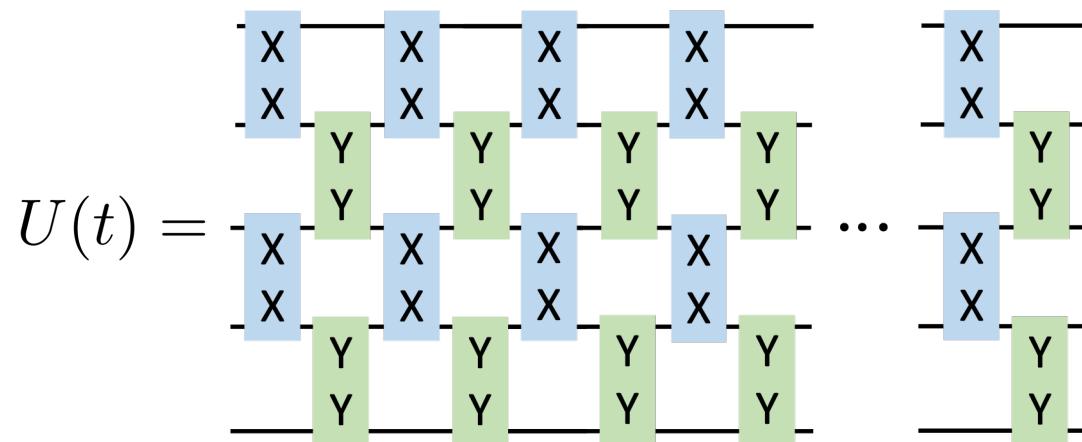

## Trotter Approximation

Consider 5 spin Kitaev chain:

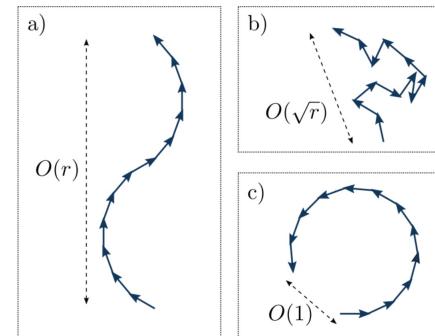

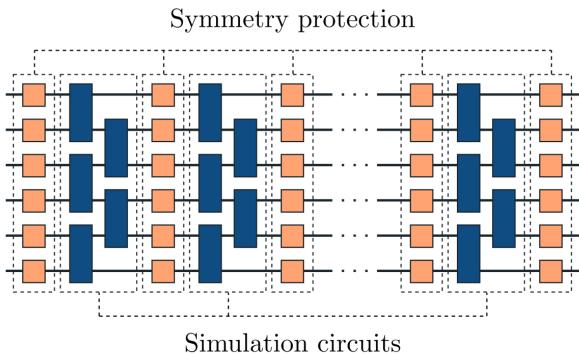

$$\mathcal{H} = a XXIII + b IYYII + c IIXXI + d IIIYY$$

$$U(\epsilon) = e^{-i\epsilon\mathcal{H}} = e^{-i\epsilon a} XXIII e^{-i\epsilon b} IYYII e^{-i\epsilon c} IIXXI e^{-i\epsilon d} IIIYY + O(\epsilon^2)$$

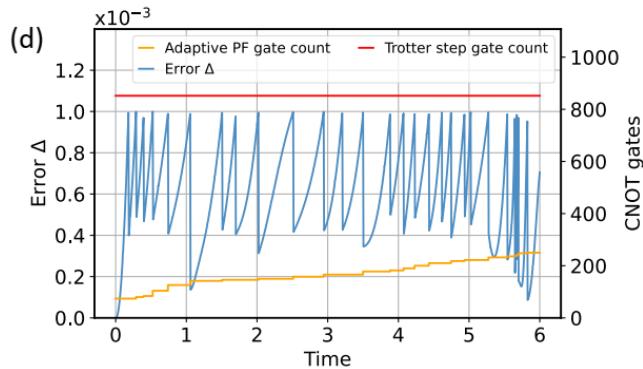

# Improving Trotter Expansions

- Symmetry protection to reduce trotter error (\*)

- Adaptive product formula to reduce number of trotter steps needed (\*\*)

$$e^{-iH\delta t}|\Psi(t)\rangle \approx T(\vec{O}', \vec{\Lambda}', t)|\Psi_0\rangle$$

## 2 Algebraic methods for circuit compression

### Cartan Decomposition

### Algebraic Compression

- Produces exact, fixed depth time evolution unitaries for any model.
- Produces unitaries for linear combinations of (anti)-Hermitian operators (UCC factors).
- We have code available!  
<https://github.com/kemperlab/cartan-quantum-synthesizer>

- Compressed Trotter circuits down to a shallow fixed depth circuit for 1-D nearest neighbor TFXY, TFIM, XY and Kitaev models.
- Based on 3 easy to check, local properties.
- We have code available! Check F3C, F3C++ and F3Cpy at <https://github.com/QuantumComputingLab>

# Approach #1: Cartan Decomposition

## Approach #1: Cartan Decomposition

Exact simulation of a time independent spin Hamiltonian:  $\mathcal{H} = \sum_j h_j \sigma^j$

Time evolution operator:

$$U(t) = e^{-it\mathcal{H}} = \prod_{\bar{\sigma}^i \in \mathfrak{su}(2^n)} e^{i\kappa_i \bar{\sigma}^i}$$

Single exponential circuit:

$$e^{i\theta IXZYI} = \begin{array}{c} \hline & & & \\ \square H & \bullet & \bullet & \bullet & \square H \\ & \oplus & & \oplus & \oplus \\ \square R & & R_z(2\theta) & & \square R^\dagger \\ & \oplus & & \oplus & \\ \hline \end{array}$$

## Main Problem

Exact simulation of a time independent spin Hamiltonian:  $\mathcal{H} = \sum_j h_j \sigma^j$

Time evolution operator:

$$U(t) = e^{-it\mathcal{H}} = \prod_{\bar{\sigma}^i \in \mathfrak{su}(2^n)} e^{i\kappa_i \bar{\sigma}^i}$$

Single exponential circuit:

$$e^{i\theta IXZYI} = \begin{array}{c} \hline & & & \\ \square H & \bullet & \bullet & \square H \\ \hline & \oplus & \oplus & \oplus \\ \square R & \bullet & \bullet & \bullet \\ \hline & \oplus & R_z(2\theta) & \oplus \\ & & & \square R^\dagger \\ \hline \end{array}$$

Two main issues:

# Main Problem

**Exact** simulation of a time independent spin Hamiltonian:  $\mathcal{H} = \sum_j h_j \sigma^j$

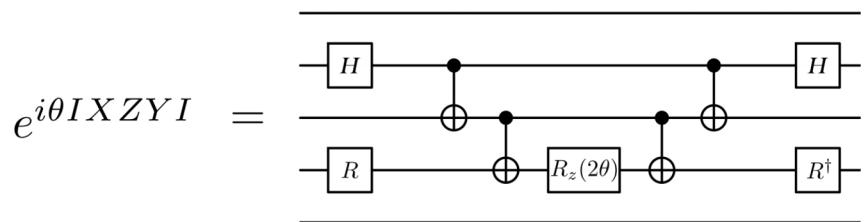

## Time evolution operator:

## Single exponential circuit:

**Two main issues:** 1)  $4^n - 1$  many  $\kappa_i$

**2) What cost function? Norm of the difference?**

$$U(t) = e^{-it\mathcal{H}} = \prod_{\bar{\sigma}^i \in \mathfrak{su}(2^n)} e^{i\kappa_i \bar{\sigma}^i}$$

# Hamiltonian Algebra

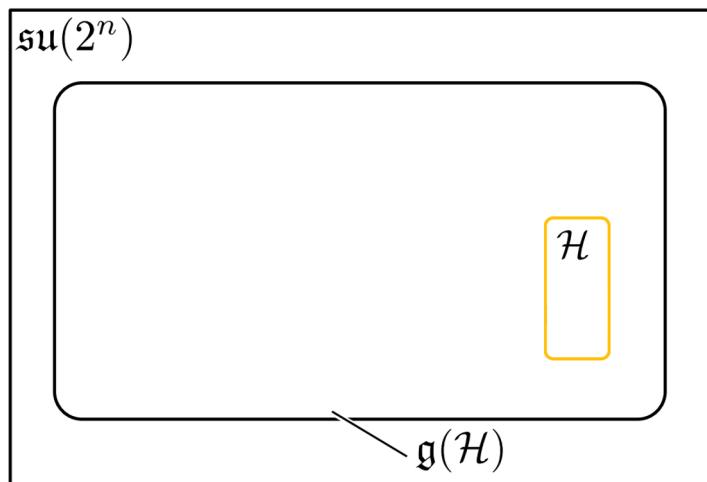

- We don't have to work in full  $\mathfrak{su}(2^n)$

$$\mathcal{H} = \sum_j h_j \sigma^j$$

$$U(t) = e^{-it\mathcal{H}} = \prod_{\bar{\sigma}^i \in \mathfrak{su}(2^n)} e^{i\kappa_i \bar{\sigma}^i}$$

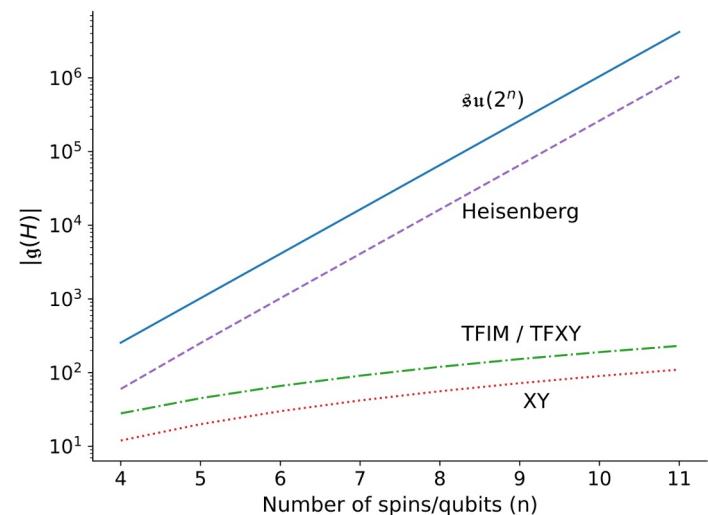

# Hamiltonian Algebra

- We don't have to work in full  $\mathfrak{su}(2^n)$
- Get the closure of the Pauli strings within the Hamiltonian under commutation i.e. the “Hamiltonian algebra”  $\mathfrak{g}(\mathcal{H})$

$$\mathcal{H} = \sum_j h_j \sigma^j$$

$$U(t) = e^{-it\mathcal{H}} = \prod_{\substack{\sigma^i \in \mathfrak{su}(2^n) \\ \bar{\sigma}^i \in \mathfrak{g}(\mathcal{H})}} e^{i\kappa_i \bar{\sigma}^i}$$

## Main Problem

Exact simulation of a time independent spin Hamiltonian:  $\mathcal{H} = \sum_j h_j \sigma^j$

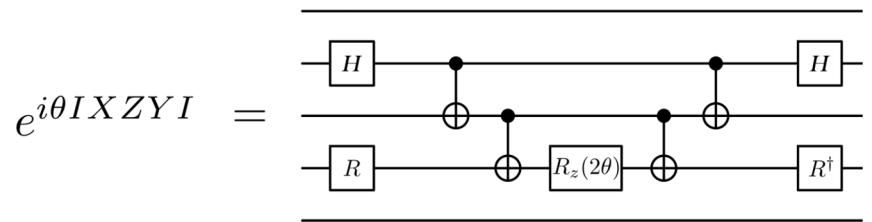

Time evolution operator is:

Single exponential circuit is given as:

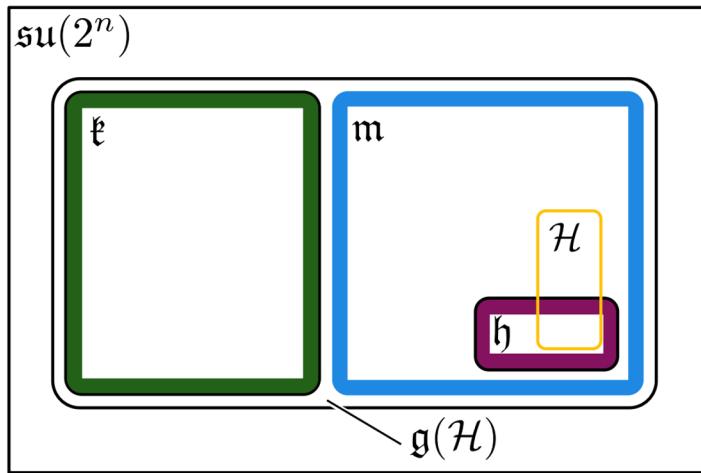

Two main issues: 1)  $4^n - 1$  many  $\kappa_i$

2) What cost function? Norm of the difference?

$$U(t) = e^{-it\mathcal{H}} = \prod_{\substack{\bar{\sigma}^i \in \mathfrak{su}(2^n) \\ \bar{\sigma}^i \in \mathfrak{g}(\mathcal{H})}} e^{i\kappa_i \bar{\sigma}^i}$$

# Cartan Decomposition and KHK Theorem

Have  $H \in \mathfrak{m}$ , and consider the following function

$$f(K) = \langle KvK^\dagger H \rangle$$

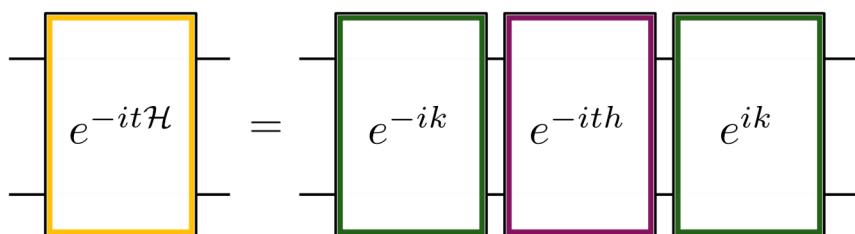

where

$$K = e^{\theta_1 k_1} e^{\theta_2 k_2} \dots e^{\theta_{n_h} k_{n_h}}$$

$$v = h_1 + \pi h_2 + \pi^2 h_3 + \dots + \pi^{n_h-1} h_{n_h}$$

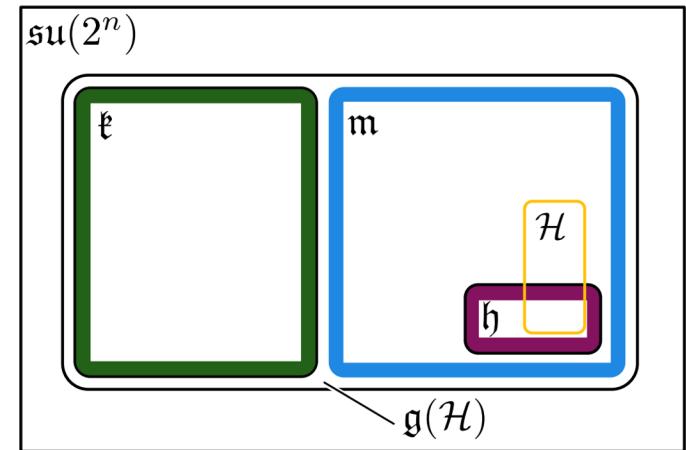

Then for any local minimum or maximum of the function  $f$  denoted by  $K_0$  will satisfy

$$K_0^\dagger H K_0 \in \mathfrak{h}$$

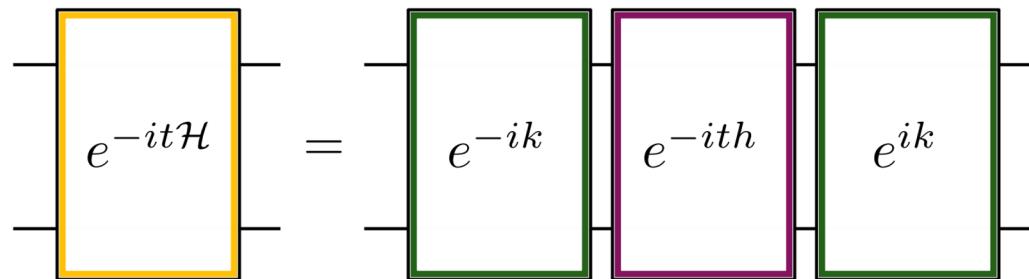

# Algorithm

- 1) Generate Hamiltonian algebra  $g(H)$
- 2) Find a Cartan decomposition where  $H$  is in  $m$
- 3) Obtain parameters via local minimum of  $f(K)$
- 4) Build the circuit using  $K$  and  $h$
- 5) Then simulate for any time you want!

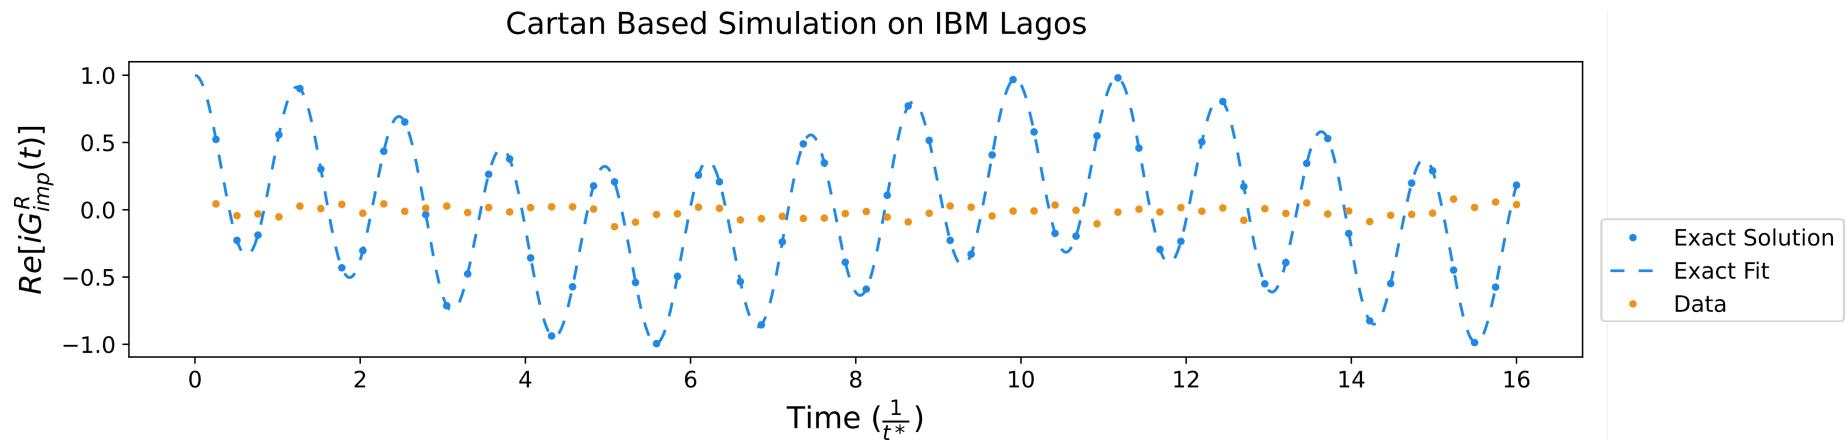

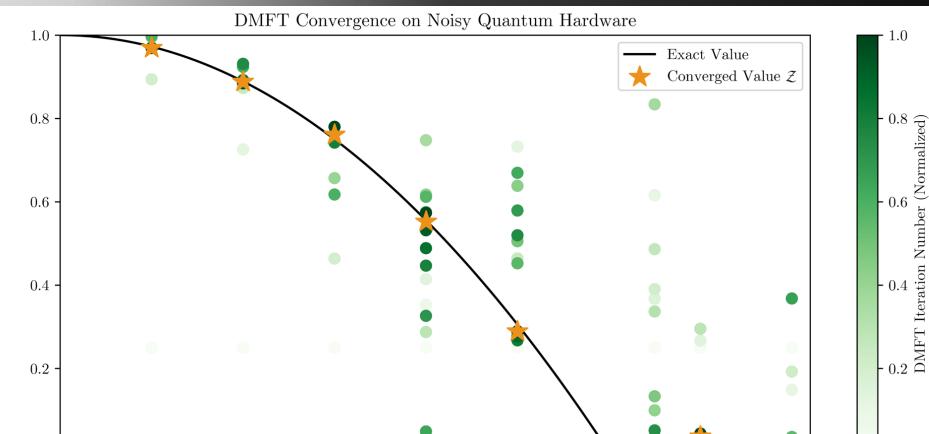

$$f(K) = \langle KvK^\dagger, \mathcal{H} \rangle$$

## Approach #1: Cartan Decomposition

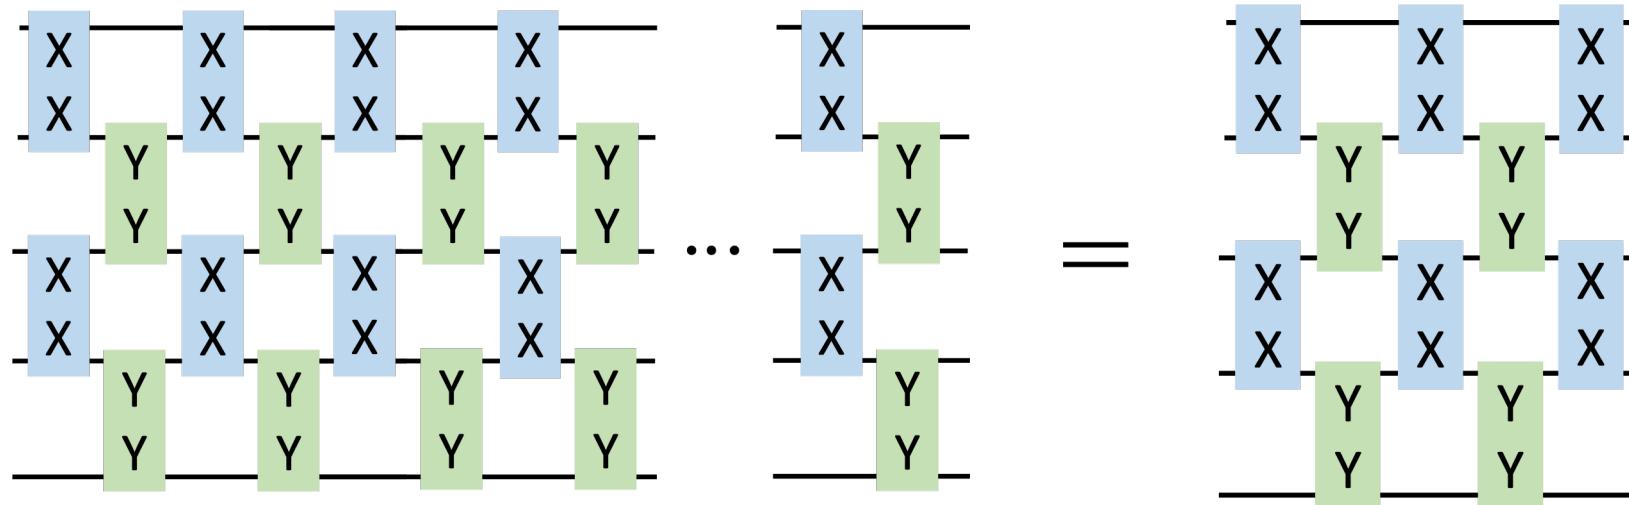

- $O(n^2)$  circuit for TFIM, TFXY, XY
- Applicable for any model
- Optimize only once for any time t
- Obtained 1<sup>st</sup> ever self-consistent DMFT Hubbard phase diagram on IBM QC.

# Approach #2: Algebraic Circuit Compression

## Approach #2: Algebraic Circuit Compression

- We propose a **constructive**, Lie algebra based method which leads to fixed depth circuits for several models
- The method is **scalable** due to its “constructive” and “local” nature.

## Approach #2: Algebraic Circuit Compression

We define an abstract object called “block” which satisfies:

**Fusion**

$$\begin{array}{c} i \\ \text{---} \\ i \end{array} = \begin{array}{c} i \end{array}$$

**Commutation**

$$\begin{array}{c} i \\ \text{---} \\ i+2 \end{array} = \begin{array}{c} i \\ \text{---} \\ i+2 \end{array}$$

**Turnover**

$$\begin{array}{c} i \\ \text{---} \\ i+1 \end{array} = \begin{array}{c} i \\ \text{---} \\ i+1 \end{array} \begin{array}{c} i \\ \text{---} \\ i \end{array}$$

Blocks will be mapped to certain quantum gates in a model specific way.

These properties are **local!** One needs to check only the neighbor gates to apply them, not the whole circuit.

## Approach #2: Algebraic Circuit Compression

### Fusion

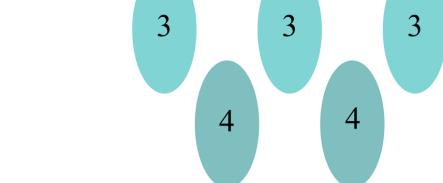

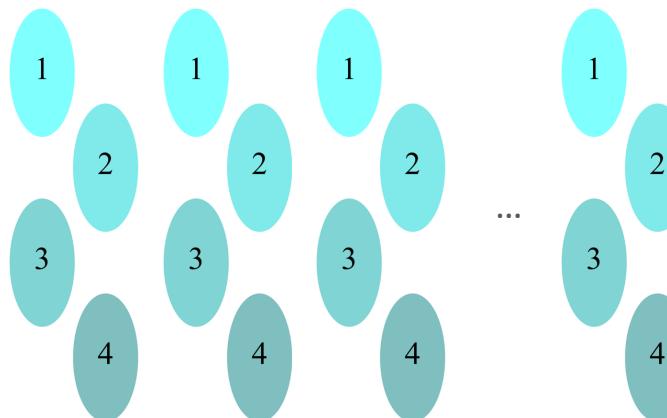

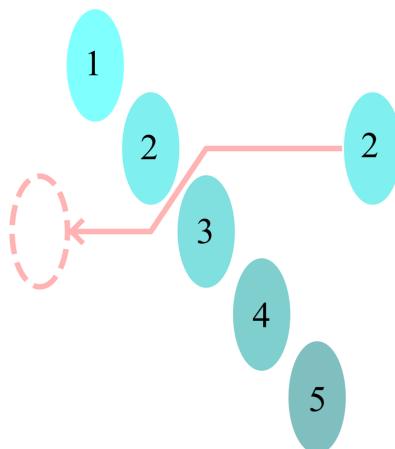

$$\begin{array}{c} i \\ \text{---} \\ i \end{array} = \begin{array}{c} i \end{array}$$

### Commutation

$$\begin{array}{c} i \\ \text{---} \\ i+2 \end{array} = \begin{array}{c} i \\ \text{---} \\ i+2 \end{array}$$

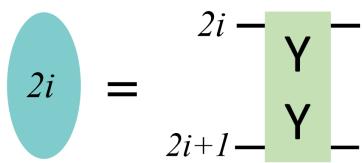

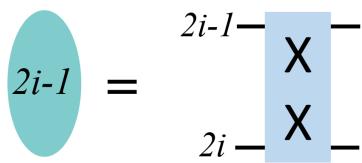

### Turnover

$$\begin{array}{c} i \\ \text{---} \\ i+1 \end{array} = \begin{array}{c} i \\ \text{---} \\ i+1 \end{array} \quad \begin{array}{c} i \\ \text{---} \\ i+1 \end{array}$$

## Examples

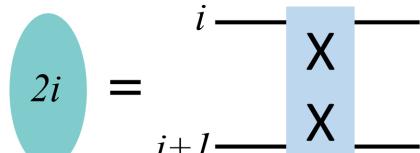

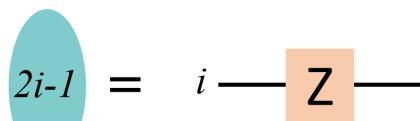

Kitaev Chain

$n(n-1)/2$  XX gates

$n(n-1)$  CNOTs

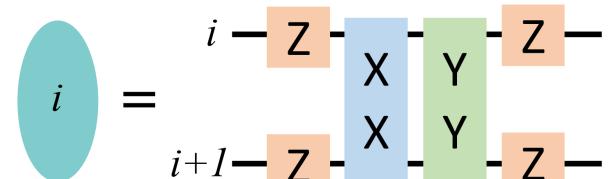

Transverse Field Ising

$n(n-1)$  XX gates

$2n(n-1)$  CNOTs

Transverse Field XY

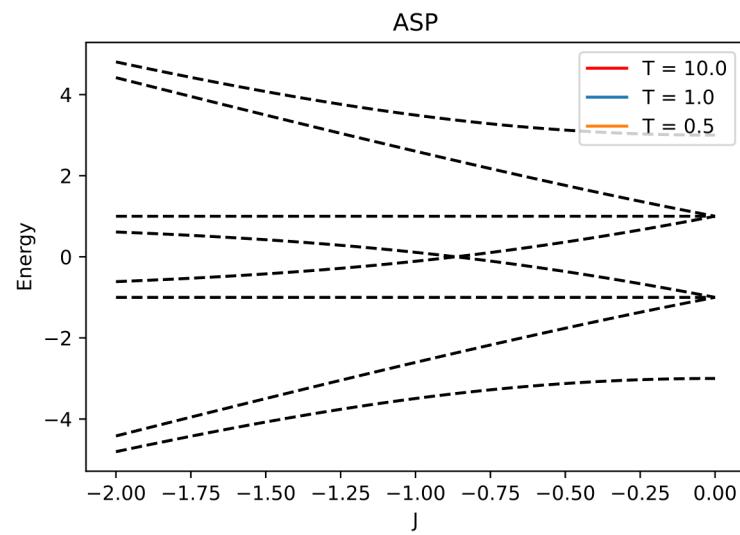

$n(n-1)$  XX gates

$n(n-1)$  CNOTs

## Main Example: Ising Adiabatic State Preparation

$$H = -2(X_1X_2 + X_2X_3) - (Z_1 + Z_2 + Z_3)$$

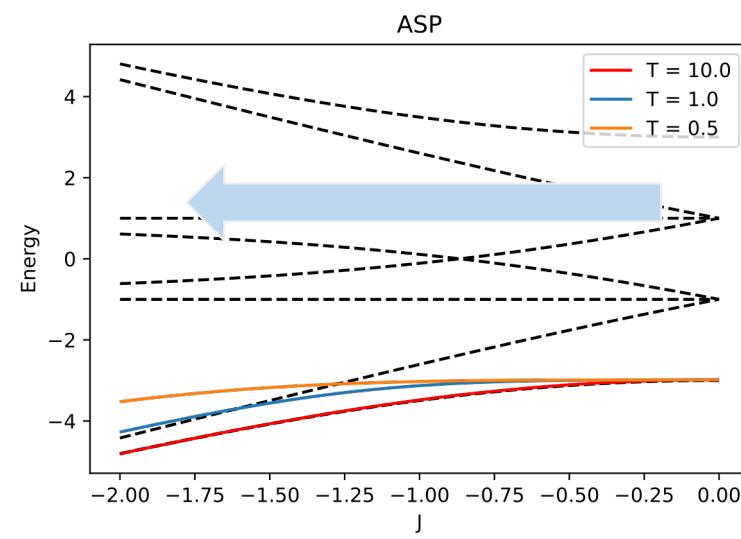

$$H = -(Z_1 + Z_2 + Z_3)$$

$$|\psi\rangle = |000\rangle$$

$$H = J(t)(X_1X_2 + X_2X_3) - (Z_1 + Z_2 + Z_3)$$

## Main Example: Adiabatic State Preparation

$$H = -2(X_1X_2 + X_2X_3) - (Z_1 + Z_2 + Z_3)$$

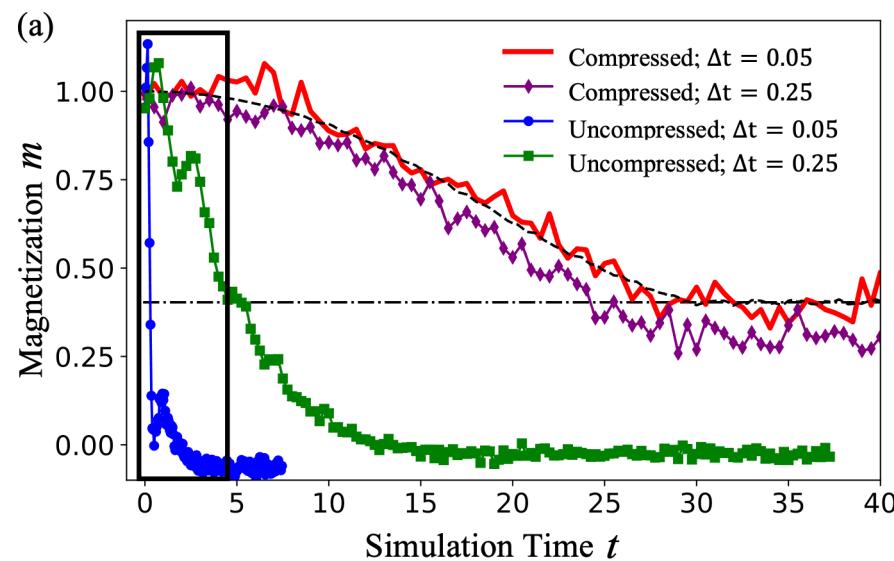

$$H = -(Z_1 + Z_2 + Z_3)$$

$$|\psi\rangle = |000\rangle$$

$$H = J(t)(X_1X_2 + X_2X_3) - (Z_1 + Z_2 + Z_3)$$

## Approach #1: Algebraic Circuit Compression

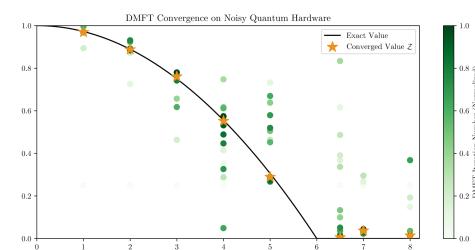

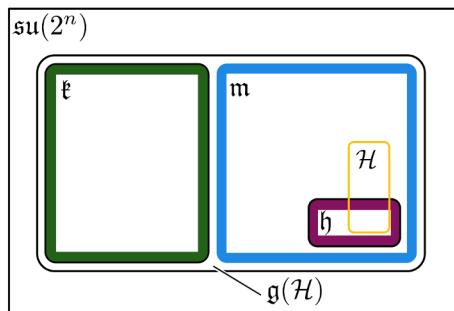

$$\mathcal{H}_{ASP}(t) = J(t) \sum_{i=1}^{n-1} X_i X_{i+1} + h_z \sum_{i=1}^n Z_i \quad \langle m(t) \rangle \equiv \frac{1}{n} \sum_i \sigma_i^z(t)$$

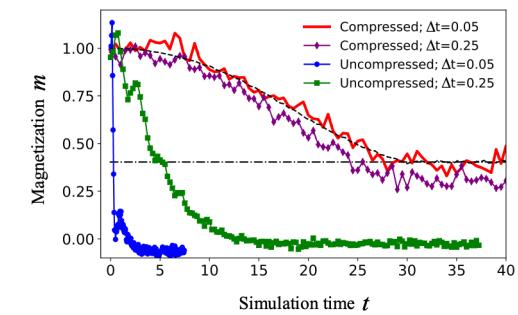

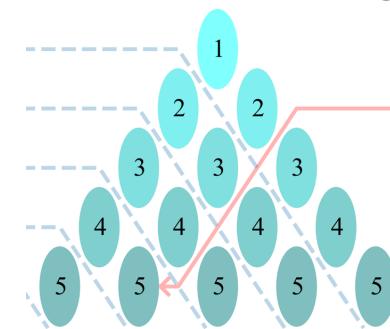

- Compressed circuits have 20 CNOT gates in total whereas Trotter circuits have increasing number of CNOTs as simulation time increases

## 2 Algebraic methods for circuit compression

### Cartan Decomposition

### Algebraic Compression

- Produces exact, fixed depth time evolution unitaries for any model.
